Abstract

Purpose: This research was done as continuation of research made previously on male population. The goal of this research is to determine „differences between morphological characteristics and motoric capabilities of physically active and inactive female students“. Material: Sample of physically inactive female students was made of 54 examinees and sample for active students was made of 52 girls. Average age was 12. All girls were primary school students. Physically inactive students regularly attended PE lessons and active students were involved in training process of basketball, volleyball, football and handball teams. Additional practice was done two times a week for 90 minutes. Morphological space is set by 15 variables and motoric space is set with 24 variables. Results: Statistical difference was determined by T-test on level (p<0.05). Significance given by T-test was checked by calculating Eta coefficient. Such data has differences in Chest Width (.00/.00 and n²=0,33), Weight (.00/.00 and n²=0,34), Stomach Skin Curves (.00/.00 and n²=0,37) and Back Skin Curves (.05/.05 and n²=0,16). Motoric space has differences in: Slalom with Three Medicine Balls (.00/.00 and n²=0,01), Throwing medicine ball from the chest (.00/.00 and n²=0,10), Long Jump (.00/.00 and n²=0,17), Push-ups (.02/.02 and n²=0,05), Sit-and-Reach (.04/.04 and n²=0,00) and 20m low start run (.00/.00 and n²=0,14). Conclusions: After analysis it can be stated the aim of the research was completed and differences of anthropological status of physically active and inactive female students were determined. Students of age 12 can be recommended additional training activity to positively transform anthropological spaces with no transformation. Research with same or similar variables should be done on different age categories when compared to this one or to analyze quality of influence that specific sports have on transformation in this age category. Keywords: primary school, additional sports activity, anthropological status, morphological characteristics and motoric capabilities.

Introduction

Research was done as continuation of already realized research with male population [1]. Given aim was to determine „differences between morphological characteristics and motoric capabilities of physically active and inactive female students“. Just like male population with same age characteristics it is determined that sedentary way of life causes different diseases. Besides, child develops system of values and learns about some valuable characteristics, positive ways of behavior and communication, changes and shapes life habits by doing sports activities. Also, several researches have shown that doing sports positively decreases number of delinquency [2]. To prevent the disease to happen, it is necessary that children are active at least 60 minutes a day with medium to energetic intensity [3, 4]. Additional negative effect for health is also the fact that when students finish their education so do they stop with process of exercises [5]. Estimated 70% of young people stops doing any kind of physical activity after they finish education. Data is confirmed by statistics done in USA where about 20 million children under the age of 14 does some kind of sport but three of four children give up those activities when they hit puberty or the age of 15 at the latest [6]. Such data shows strong negative influence of sedentary way of life so it is recommended that children choose their sports activities individually and what interests them so they will be highly motivated to practice [7, 8]. According to some theoreticians, developing period of a 12-year-old is characterized by proportional emotional stability when compared to some other growing stages [9], so this life period should be properly used to promote and apply sports activities. Physically inactive female students have regularly attended PE lessons two times a week and those who were physically active had additional training activities outside of school also two times a week. Activities lasted for 90 minutes and selected sports were basketball, volleyball, handball and football. Since physically active students practice 4 times a week it is assumed their anthropological status is on higher development level than inactive students who practice 2 times a week [10, 11]. For a student to be considered as athlete it is necessary to spend one year in training process. Students who participated in research are the same age so result of morphological and motoric transformation status can be a cause of ergogenic factors

doi:10.15561/18189172.2020.0105
that is transformational processes which are result of sports clubs training [12]. Results of this research should determine higher level of morphological and motoric status development for physically active students and confirm increased movement activity which positively affects transformation of morphological characteristics and motoric capabilities. Research like this is important since it finds out different ways to increase movement activities of female students and decreases negative effects of sedentary way of life [13].

**Material and Methods**

**Participants**

Examinee sample are primary school girls from the area of Srednjebosanski Canton in Bosnia and Herzegovina. Average age is 12 years ±1 months. There were N= 54 of physically active female students. N= 52 is the number of physically active female students. According to Helsinki Measuring and Testing Propositions, student, parent and teacher permissions were given to do this tests. Only students who were completely healthy during the research could participate. Students could leave the research at any time.

**Research Desing**

Variables of morphological status are gathered in a way described by authors Šoše, & Rađo [14] and measured: Body Height (VIST), Arm Length (DUZRUK), Leg Length (DUZNOG), Shoulders Width (SIRRAM), Pelvic Width (SIRKARL), Hand Width (SIRSAK), Foot Width (SIRSTOP), Middle Size of Chest (OGRU), Size above knee (OBNTK), Size above elbow (OBNDL), Back Skin Curves (NBLED), Stomach Skin Curves (NBTRB), Above Elbow Curves (NBNDL), Above Knee Curves (NBNTK), Body Mass (MASTJ).

Variables of morphological status are gathered in a way described by authors Držačić et al. [15] and Mikić [16] and measured: Bat Coordination (KOOPAL), Slalom with three medicine balls (SLA3MED), Low Eights (OSMSAG), Throwing medicine ball from laying position (BACMED), Long Jump (SKOKLJ), 20m running (TRC20M), Leg Tapping (TAPNOG), Leg Tapping against the Wall (TAPNOGZ), Hand Tapping (TAPRUK), Push-ups on Loom (SKLEK), Sit-ups (LEZSJED), Deep Sit-ups with Pressure (CUCANJ), Standing on one leg on a bench with open eyes (OTVOCIUZ), Standing on one leg on a bench with closed eyes (ZATVOCIP), Standing on one leg on a bench with closed eyes (ZATVOCIP), Aiming with long stick (CILJUGST), Leg pointing to vertical aim (CILJVERT), Hand pointing to horizontal aim (CILJHOR), Bat Turn (ISKRJPA), Laying on chest throw (ZANLEZGRU), Deep carry on bench (PRETKL), 20m running from high start (TRC20VISST), 20m running from laying start (TRC20ZST), 20m running from flying start (TRC20ETZST).

**Statistical Analysis**

Gathered data was analyzed in SPSS 22 program with license from Faculty of Sports and Physical Education, University of Sarajevo. Difference between groups was determined with T-test for independent samples on statistical significance level P< 0.05. Values above stated ones were not considered as statistically relevant. Significance of T-test up to 0.05 was checked by calculating eta coefficient about variant coverage between group results. Calculating of eta coefficient (η2) was done according to Cohen, [17] and Kolesarić, & Tomašić-Humer, [18]: .01 – high coverage; .06 – medium coverage; .13 – small coverage of variant.

**Results**

Taking into consideration statistical indicators, one must state that results show only variables where there is clear descriptive statistical difference. Variables are additionally marked with number 1 of inactive students group whereas variable under number 2 (Table 1) are for active athletes group. Presented variables are normally distributed and suitable for further analysis. Table 1 shows that minimum and maximum group results have appropriate differences. Chest size in minimal (62 > 58.2) and maximum (86.1 > 79.2) result is higher on athletes while weight is lower (min.30 < 31.2 and 43.4 < 45.3) which can indicate „athletic body construction of this group “. Two measures of skin fat mass are also lower on athletes (NBTRBmin. 1.0 < 2.0 and NBTRB max. 9.0 < 15.0, NBLEDmin. 1.0 = 1.0 and NBLED max. 13.0 < 17.0). When it comes to variables of motoric space, all variables presented by time component are „opposite “values and are lower in group of athletes which in this case is better result (SLA3MEDmin 20.5 < 22.5, SLA3MEDmax 42.3< 54.3, TRC20min 4.1< 4.2, TRC20max 5.3 < 6.6).

When morphological variables that had descriptive statistical difference were analyzed by T-test, four of them had differences. Those variables are: OBGRK whose result standard deviation is: 5.920/5.614 (Table 2) and do not exceed relation 1:1.5. Value Sig2 is .000/.000 with significant difference between results. Sig1 value .637 assumes difference between group results which confirms calculated eta coefficient .033. Variant coverage is small – results are different.

TEZ results in Standard Deviation (13.09/9.09) do not exceed relations 1:1.5. Values Sig2: .000/.000 indicate there is a difference between groups. Sig1 value .637 indicates that group results are not homogenous. After checking variant coverage of eta coefficient η2=.034 it can be stated that there is a small variant coverage and big difference in weight measures.

NBTRB in Standard Deviation (1.857/2.994) does not exceed relations 1:1.5 and shows homogenous results in groups and confirms normal distribution of results. Results Sig2 value: .000/.000 indicate there is a difference between results. However, Sig1 value (.002) is somewhat higher than first two variables and is closer to limit of T-test significance. Checking results by calculating eta coefficient (η2=.037) makes us state low coverage of variants and one can confirm significance of T-test differences for this variable.

NBLED in Standard Deviation (2.696/3.836) exceeds relations 1:2. Data shows that measured group results are...

not homogenous. Values Sig2 .057/.051 indicate there is a significant difference between results. Sig1 value is .055 so one can assume that difference will be confirmed by T-test. Additional calculating of eta coefficient η2=.16 confirmed border value about difference in variant coverage. However, it can be stated that present values go in favour of athlete female students for this variant.

T-test has shown that motoric capabilities have statistically significant difference in six variables: SLA3MED that in Standard Deviation (Table 3) 5.095/6.381 exceeds relation 1:3. Data shows higher difference in result variants and they are not homogenous. Values Sig2 .033/.033 in Table 3 show difference between groups and are confirmed after insight in Sig1 .174. Checking coverage of variant with eta=.01 confirmed high coverage of results. Results between groups are not different.

**BACMED** in Standard Deviation is 38.241/44.755 and does not exceed values 1:1.5. Data shows low result coverage. Values Sig2 .003/.003 and Sig1 .986 show statistical significance of differences. By calculating eta coefficient η2= 0.14 border low result coverage between groups is confirmed so the result is better for athlete female students.

**SKOKD** in Standard Deviation is 12.289/9.325 and does not exceed values 1:1.5 so group results are confirmed. Values Sig2: .001/.001 and Sig1: .056 show statistically significant differences between group results. Calculating eta coefficient η2= .17 confirms low result coverage which shows that SKOKD is better realized within athlete female students.

**SKLEK** in Standard Deviation is (3.722/3.846) and

Discussion

Numerous researches have established that additional movement activity affects more developed anthropological status [19, 20, 1, 21]. Second important factor is cognitive readiness and child’s capability to understand reasons why sport is important which is a characteristic of a 12-year-old population [22]. Because of that, determining influences of additional movement activity on anthropological status transformation of primary school female students is organized and this research was done.

Difference between anthropological statuses was checked for morphological characteristics and motoric capabilities. Even though large number of morphological variables was examined – 15 to be exact, after final T-test determination and calculation of eta coefficient, this research presented only four of them. Given procedure was done since there was a difference shown by T-test and additionally checked by calculating eta coefficient for each of above mentioned variables. Only variables with low result coverage and high eta coefficient (η2) were accepted as significantly different. Such criteria were insisted upon because values of T-test have been set on border level (p<0.05).

Morphological characteristics checked by T-test have shown differences in: Chest Size (OBGK), Weight (TEZ), Stomach Skin Curves (NBTRB) and Back Skin Curves (NBLED). Everything indicates that additional sports activity realized through training process of games has influence on lower body weight and less skin fat tissue on female athletes (Witt and co. 2005). This data is not so important for back skin curves which is surprising since other variables should be significantly lower on female athletes. Given result is not in accordance with research results done by [23, 24, 25].

Same work methods were applied on motoric capabilities as well as morphological characteristics when it comes to result representation in this research. T-test has shown significant development in six variables: SLA3MED, BACMED, SKOKD, SKLEK, LEZSJED and TRC20. To check significant difference given by T-test, variant coverage for each of these variables was done. Variables with low result coverage have been accepted as significantly different. It can be stated that three variables had low result coverage that is eta coefficient was calculated (η2). Throwing medicine ball from chest (BACMED), Long jump (SKOKD) and 20m running from low start (TRC20) are better developed on athlete female students. The rest of the variables in motoric space do not show statistically significant difference. Given results are in accordance with research done by [26, 27] as well as research by authors Đukić, et al. [28] and Vrbik, et al. [29]. Thanks to additional sports activity of two times a week per 90 minutes, female active athletes have had certain transformation of motoric and morphological status. However, it can be stated because of calculated eta coefficients that there was bigger transformation on morphological characteristics [30, 31]. Also, one can claim that research aim was completed and „differences...
between morphological characteristics and motoric capabilities of physically active and inactive female students” were determined. Weakness of this research can be seen in the absence of insight into adjustment of training activities to age group of examinees in this research. Students should give additional data about their nutrition and free time movement. Research could be organized and done on different age or sex categories and all given data would give additional knowledge about existence of determined differences.

Conclusions

Thanks to additional sports activity of two times a week per 90 minutes, female active athletes have had certain transformation of motoric and morphological status. However, it can be stated because of calculated eta coefficients that there was bigger transformation on morphological characteristics. Also, one can claim that research aim was completed and “differences between morphological characteristics and motoric capabilities of physically active and inactive female students” were determined. Weakness of this research can be seen in the absence of insight into adjustment of training activities to age group of examinees in this research. Students should give additional data about their nutrition and free time movement. Research could be organized and done on different age or sex categories and all given data would give additional knowledge about existence of determined differences.
